

Multifactor Authentication(MFA):

Multifactor authentication, or MFA, is an IT security technology method that requires an individual to provide two or more authentication factors to confirm his identity for online transactions or to gain access to corporate applications, networks and servers. Multifactor authentication benefits include tighter security and user identity protection to avoid phishing scams. The goal of multifactor authentication methods is to increase the difficulty for an adversary to exploit the login process and roam freely around personal or corporate networks and compromise computers to steal confidential information. Multi-factor authentication is used to ensure that digital users are who they say they are by requiring that they provide at least two pieces of evidence to prove their identity. Each piece of evidence must come from a different category: something they know, something they have or something they are.

MFA makes it difficult for an attacker who has your password to access your account or breach systems. Multi-factor Authentication (MFA) is an authentication method that requires the user to provide two or more verification factors to gain access to a resource such as an application, online account, or a VPN. Rather than just asking for a username and password, MFA requires one or more additional verification factors, which decreases the likelihood of a successful cyber-attack. The main benefit of MFA is it will enhance your organization's security by requiring your users to identify themselves by more than a username and password. While important, usernames and passwords are vulnerable to brute force attacks and can be stolen by third parties. Enforcing the use of an MFA factor like a thumbprint or physical hardware key means increased confidence that your organization will stay safe from cyber criminals.

MFA works by requiring additional verification information (factors). One of the most common MFA factors that users encounter is one-time passwords (OTP). OTPs are those 4-8-digit codes that you often receive via email, SMS or some sort of mobile app. With OTPs a new code is generated periodically or each time an authentication request is submitted. The code is generated based upon a seed value that is assigned to the user when they first register and some other factor which could simply be a counter that is
